complex systems.

The type of Availability that is of interest in this article is the Intrinsic Availability (Ai), which is a measure of the availability of a system in the hypothesis of ideal logistic support I.E. unlimited supplies, instant transportation time, unlimited manpower and so on. Ai is a necessary condition for the generation of the Operational Availability (Ao), which is the result of the Availability Assessment process.

As highlighted by some studies of the USA DoD, the Availability Assessment process hasn't received any major innovation since many decades and is now starting to show its age. Through many of these studies, the DoD has evidenced that common reliability and availability analyses will gradually become less effective. The reason of this has been identified in the lack of analysis of the "mechanisms" that causes a fault in an item and ultimately in the system.

A proposal to update LSA databases for an Operational Availability based on Autonomic Logistic.

Abstract – This article analyzes a possible extension of the modern Logistic Support Analysis (LSA) databases such as ASD S3000L in order to support a new view of operational availability based on the categorization of stresses obtained by operational scenarios and applicable to FMMEA (Failure Mode Mechanism Effect Analysis) through the "physics of failure" concept. In order to integrate such methodologies inside the actual ILS (Integrated Logistic Support) process, new database parameters and stress/failure physics categorization classes needs to be defined. This article discusses this problematic and proposes some extensions of the ASD S3000L LSA data model.

Keywords— Operational Availability; FMMEA; S3000L; Autonomic Logistic.

This approach is reflected by the standardized database structure described by the most of the recent international standards for the management of LSA of which the newest is ASD/AIA S3000L; that defines precisely the main "data containers" which have to be used to store and manage such information. The main characteristic is however that most of the data used are derived from historical series collected during the systems life cycle, which represents a measurement of the system characteristics but do not take into consideration the "mechanisms" which governs such data.

The approach is recently showing many limits [4],[5],[6] in the effectiveness of complex system modeling especially when compared with:

Advanced 3D Manufacturing

The idea concerns the possibility to directly embed commercial chips and deposit highly conductive nano-materials during fabrication, (especially for the internal paths of the device), locally reducing the manufacturing process to fabricate 3D applications for several purposes (antennas for communications, automotive active parts, smart sensors, customized electronics, etc.).

Advanced 3D Manufacturing

Directly embed commercial chips and deposit highly conductive nano-materials during fabrication, (especially for the internal paths of the device), locally reducing the manufacturing process to fabricate 3D applications for several purposes (antennas for communications, automotive active parts, smart sensors, customized electronics, etc.).

Laser engraving technique, implemented on plexiglass to tailor both conductive paths and chip housing. The device is part of the Italian patent developed by Se.Te.L., Unoauto and IMM-CNR
